

Shocking Offers: Gender, Wage Inequality, and Recessions in Online Labor Markets*

November 20, 2023

Abstract

Using data from the largest online job portal in Nigeria, we document: (a) gender differences in salary offers for jobs, and (b) the response of (a) to recessions. Jobs in industries where the number of job applicants skews female, offer lower starting salaries than jobs in industries where applicants skews male. During Nigeria's 2016 recession, applications to jobs in industries that skew female fell, and salary offers rose. In contrast, applications to jobs in industries that skew male rose, and salary offers fell. In accordance with this relative shift in applications, in 2016, the salary-offer gap almost disappears.

1 Introduction

Economists care about discrimination in the labor market because it reduces productivity and standards of living. Between 20 and 40 percent of the increase in output per person in the United States between 1960 and 2010, for example, is explained by a more efficient

allocation of workforce talent, and a significant fraction of that reallocation stemmed from a reduction in labor market discrimination against talented women and Black men (Hsieh et al., 2019).

Yet most of what economists know about discrimination in labor markets comes from advanced economies, where the size of the labor force is stagnating in absolute terms and shrinking relative to the size of the global labor force. We know far less about the impact of labor market discrimination on the economic efficiency of countries in Sub-Saharan Africa, whose current number of labor market participants—600 million—will double by 2050, and quadruple by 2100, at which time the region will account for 40 percent of world labor (Lam 2019). To understand the future consequences of labor market discrimination on the global economy we must understand its impact in Africa.

This paper provides a step forward by presenting the first systematic set of facts about the market for highly compensated employees in Nigeria and examining whether these facts suggest that Nigerian employers discriminate against women. Nigeria is a natural place to pursue this line of research for two reasons. First, with a working age population that will expand from 106 million in 2020, to 244 million in 2050, Nigeria is the world’s seventh largest labor market, and the epicenter of the explosion in the size of Africa’s workforce. Second, recent research suggests that women in Nigeria face obstacles to participation in the labor market. They are less likely to apply for senior level jobs than men, despite being equally qualified, and women are less likely to be hired (Archibong et al., 2022).

Is gender discrimination operative in the Nigerian labor market? If the Nigerian labor market efficiently allocates male and female talent, then we would expect the cross-sectional variation in the level of human capital of male and female Nigerian employees to explain the cross-sectional variation in the level of their salaries (Mincer, 1958). The challenge with examining this link, however, is the paucity of knowledge on salaried employees in Africa

(Bandiera et al., 2022)

We begin filling the knowledge gap by using data from Nigeria’s largest online job portal between May 2014 and May 2020 to compile the first comprehensive dataset on salaried employees in Nigeria. Relative to previous studies of African labor markets, our data contains unique features that allow us to directly examine questions of efficiency. For every given job posting, for instance, Table 1 provides data on: (a) the size of the firm that posted the job—87 percent are small and medium-sized enterprises with 100 workers or less; (b) industry; (c) level of seniority; (d) the employer’s list of preferred qualifications; and (e) the minimum-to-maximum salary range.

Likewise, for every application submitted for a given job posting, Table 1 provides data on the applicant’s age, experience, years of schooling, age, and gender. The average age of applicants is 31. They average 4.5 years of experience. Seventy-nine percent of participants in the portal are college graduates or higher, and ninety-eight percent have some tertiary education. The share of female applicants on the platform is 33 percent, a figure that is consistent with other studies of online labor markets in Africa (Archibong et al., 2022). 55% of the jobs are in male-skewed industries, those industries where most applicants are men. Figure 1 provides a full breakdown of industries by gender skew.

If men and women have similar salary preferences, and Nigerian employers behave in a Mincerian fashion, then controlling for differences in the education, skill level, and experience of job applicants, gender will not be correlated with salary offers. Figure 2 provides an ocular test of this prediction—Section 3 examines it econometrically—by plotting salary offers for jobs according to the gender skew of the pool of applicants to those jobs. The figure does not support the prediction that gender and salary offer are uncorrelated. In 2014, the average salary offer for jobs in industries where applications skew male (orange line) was roughly 400,000 Naira per month. Since the average monthly exchange rate for Nigeria in 2014 was

165 Naira per US dollar, this salary amounts to \$2,424 per month, or \$29,090 per year. In contrast, the average salary offer for jobs in industries where applications skew female (blue line) was about 240,000 Naira (\$1,455) per month, or three-fifths of the average offer for jobs in industries that skew male. As GDP per person in Nigeria is about \$2,280 per year, the annual incomes implied by the average salary offers for both male and female workers are much higher than the income of the average Nigerian.

Figure 2 also documents the response of salary offers to two recessions. From the middle of 2014 through early 2016, the real price of oil fell by 70 percent (World Bank 2018). This exogenous shock to Nigeria’s principal export reduced growth in 2015, caused GDP to contract by 1.6 percent in 2016, and had attendant consequences for the labor market. Unemployment rose from 7.8 percent in 2014 to 17.5 percent in 2017. During Nigeria’s 2016 recession, the number of applications to jobs in industries that skew female fell. The number of applications to jobs in industries that skew male rose. In accordance with this relative shift in the number of applications, the salary-offer gap fell sharply and virtually disappeared in 2016.

As the economy recovered, the salary-offer gap re-widened, but less dramatically, before narrowing again with the onset of the COVID-19-induced recession of 2020. The information we have on salary offers for 2020 does not cover the full year, but the facts from 2016 suggest that recessions may increase the bargaining power of groups like women who are under-represented in the labor market, while decreasing the bargaining power of those in the majority.

2 Data

The online hiring platform consists of 227,194 unique applicants, 63,692 job listings, and 2,281,118 applicant-job matches. 83% of the job listings are in major cities from 3 states in Nigeria: Lagos (70%), Abuja (11%) and Rivers (2%) (Archibong et al., 2022). How

representative are the jobs on the online platform of the general labor market in Nigeria? As expected, Agriculture, the largest employment category in Nigeria, is underrepresented, given the urban focus of online job listings.¹ The proportions of other industries, like Consulting, Construction, and Manufacturing are comparable to the national level labor statistics. ICT, Banking/Financial Services and Trade jobs are overrepresented.

Table 1 shows that the jobs require about 2.6 years of work experience and a higher national diploma or 1-2 years of post-secondary education on average. Senior level jobs, at the experienced non-manager level or higher, make up about 73% of the applied to listings. Job listings also include a range of salary offers. Minimum salary offers in female-skewed industries are significantly lower (43% lower), on average, than salaries in male-skewed industries.²

3 Empirical Strategy and Results

How do recessions, specifically, Nigeria’s 2016 oil recession, affect the industry gender gap in salary offers apparent in Figure 2? To focus on the effects of the 2016 recession, we limit the sample to job postings between 2014 and 2019, and use a regression of the following general form:

$$Y_{idst} = \alpha \text{Female-skew Ind.}_{ids} + \beta \text{Recession}_t + \gamma \text{Female-skew Ind.}_{ids} \times \text{Recession}_t + \mathbf{X}'_{idst} \tau + \phi_s + \epsilon_{idst} \quad (1)$$

where i and d index the individual job listing and industry respectively. s is the location of the job listing in one of Nigeria’s 37 administrative states³ or outside of Nigeria, and t is the

¹Source: 2017 Nigerian National Bureau of Statistics (NBS) data.

²Average minimum monthly salaries in female-skewed industries are about 106,000 Naira versus 185,000 Naira in male-skewed industries.

³36 states plus the capital at Abuja.

date or year of the job posting. The outcomes of interest include the minimum salary offer posted by the employer on the job listing, and the number of applications the job listing receives. Female-skew Ind. is an indicator that equals 1 if the job listing is in a female-skewed industry and 0 otherwise. Recession is an indicator that equals 1 if the job was posted during the recession year in 2016. Our key parameter of interest is γ . This measures the effect of the 2016 recession on salary offers and number of applications in female-skewed relative to male-skewed industries. All regressions include job listing level controls for the job required education and years of experience, job type (full time or other) and job level, \mathbf{X}'_{idt} , and job location fixed effects.

Column (1) of Table 2 indicates that while job listings in female-skewed industries in non-recession years offer roughly 99,000 Naira (\$495 per month in 2016) less on average, during the recession, jobs listed in female-skewed industries paid 85,000 Naira more than jobs in male-skewed industries, a 55% increase in relative salary offers relative to the mean. In contrast, salary offers in male-skewed industries fell by 125,000 Naira during the recession. Overall, during the recession, jobs in female-skewed industries offer just 14,000 Naira (\$70) less in monthly salary, a near closing of the industry gender gap. Column (2) shows that during the recession applications to jobs in female-skewed industries fell; applications to male-skewed industries rose.

Do the results in Column (1) of Table 2 suggest that Nigerian employers discriminate against women, or do they reflect the reality that Nigerian women prefer to work in industries with a constellation of jobs that offer lower pay? Jobs in information, communications, and technology (ICT) pay more than jobs in education. If highly educated Nigerian women prefer to work as teachers rather than coders, for example, then the results might spuriously suggest employer discrimination is operative when the salary-offer gap simply reflects that women prefer teaching to coding.

To determine whether the salary-offer results reflect industry-specific discrimination against women by employers, or industry-specific preferences for employment by women, we report in columns (3) and (4) of Table 2 the results of running an additional set of regressions. These regressions test whether, for the same job, salary offers by employers reflect a gender-specific industry skew. Specifically, Columns (3) and (4) of Table 2 report the results of regressions from Equation 1 limiting the sample to job listings for accountant job roles only. The logic of this regression is as follows. The work of accountants is largely invariant to the industry in which they are employed. Therefore, if employers do not take into consideration the gender skew of the industry when making salary offers for jobs, then the gender-skew of the industry in which applicants apply for accounting jobs should be statistically and economically insignificant in the accountant-specific salary regression. This is not the case. Table 2 and Figure 2(c) indicate that the accountants results mimic the main results in Column (1).

4 Conclusion

For countries to develop, the organization of labor markets must shift from informal self-employment to formal salaried jobs. Because the Nigerian dataset used in this paper is the first large scale source of information on salaried employees in Africa, it provides a foundation for beginning to understand whether formal labor markets in the region behave in accordance with standard models.

Holding constant the education and years of experience they require of applicants for a given job listing, Nigerian employers systematically offer higher salaries for jobs listed in industries where the applicants for jobs skew male than they do in industries where the applicants skew female. This salary-offer gap cannot be explained by a preference of female candidates for jobs in industries that happen to have lower pay, and the gap decreases during recessions. There may be alternative explanations of our results, but the facts in this paper

do not support the view that Nigerian employers make gender neutral salary offers based exclusively on the education, skills, and experience of applicants. Future work can build on these results to create a set of stylized facts about the extent to which one of the world's largest and fastest growing labor markets functions efficiently.

Figure 1: Gender skew in online applications by industry, 2014-2020

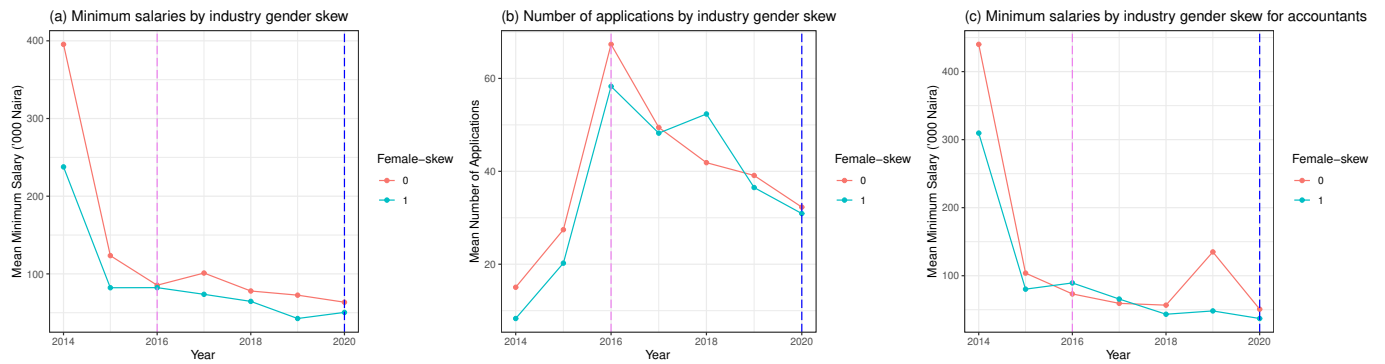

Figure 2: Salary offers in industries where job applications skew male are higher than in those that skew female

Table 1: Summary statistics: The online job portal captures a significant fraction of the universe of highly educated Nigerian workers

Variable	N	Mean	St. Dev.	Min	Max
